

Quantitative Macroeconomics

Financial Frictions and Development: Midrigan & Xu (2014)

Tomás R. Martinez

UnB

Introduction

- Large differences in TFP across countries.
- Many have shown that dispersion in MPK can go a long way in explaining these differences..
- Financial markets are much less developed in poor countries \Rightarrow Potential source of misallocation!
- Financial frictions can distort the economy in two ways:
 - ▶ **Extensive Margin**: Entry or technology adoption;
 - ▶ **Intensive Margin**: Misallocation of resources among operating producers.

Introduction

- M&XU: Financial frictions can have large effects on TFP, but these effects are mostly from the **extensive margin**.
- Why FF cannot generate strong misallocation among existent producers?
 - ▶ They accumulate internal funds and *un-do* the effects of financial frictions.
- Financial frictions might also be useful to generate micro behavior consistent with the data:
 - ▶ Larger growth from young firms.

Model Setup

- Model is populated by a measure one of workers and a measure N_t of producers.
- Efficiency of labor grows at rate $\gamma > 1$ (i.e., it is a growth model);
- **Two sectors:** traditional and modern sector.
- **Traditional:** only labor and an unproductive technology.
- **Modern:** capital and labor, productive technology, requires upfront investment (entry cost).
- A measure of $(\gamma - 1)N_t$ producers enter every period. All producers enter in the traditional sector.

Model Setup

- Workers and Producers are heterogeneous in their net worth and productivities.
- They have log preferences over consumption:

$$\mathbb{E}_0 \sum_{t=0}^{\infty} \beta^t \log(C_t)$$

- Producers productivity has two dimensions:
 - ▶ z : permanent (fixed) productivity;
 - ▶ e : transitory productivity that follows a Markov process with probabilities f_{ij} ;
- Entrants start with zero net worth and draw productivities from their invariant distribution.
- Workers' labor productivity ν_t follows a finite state Markov.

Traditional Sector

- Production function uses only labor: $Y_t = \exp(z + e)^{1-\eta} L_t^\eta$, where $\eta < 1$.
- Producers in the traditional sector choose consumption-savings and whether to enter the modern sector.
- If they stay in the traditional sector, their budget constraint is:

$$C_t = Y_t - WL_t - (1 + r)D_t + D_{t+1}$$

where $D_{t+1} \leq 0$ is their debt position. They cannot borrow.

Traditional Sector

- If they enter the modern sector, they must finance expenditure on physical capital K_{t+1} and intangibles $\exp(z)\kappa$. To finance it, they can use their own funds, borrow or issue equity.
- The producer who enters can borrow up to a certain limit of its capital (collateral):

$$D_{t+1} \leq \theta(K_{t+1} + \exp(z)\kappa).$$

where $\theta \in [0, 1]$ governs the strength of financial frictions.

- Producers can issue claims to a fraction $\theta\chi$ of their future profits (equity), where $\chi \in [0, 1]$.
- The budget constraint of a entrepreneur entering in the modern sector is:

$$C_t + K_{t+1} + \exp(z)\kappa = Y_t - WL_t - (1+r)D_t + D_{t+1} + \theta\chi P_t$$

where P_t is the price of a share.

Traditional Sector

- Let net worth be: $A = K - D$. Divide everything by $\exp(z)$, i.e. $a \equiv A / \exp(z)$.
- The Bellman equation of the producers in the traditional sector is:

$$\begin{aligned} V^{\tau}(a, e) &= \max_{a', c} \log(c) + \beta \max \left\{ \mathbb{E}[V^{\tau}(a', e')|e], \mathbb{E}[V^m(a', e')|e] \right\} \\ \text{s.t. } c + x &= \pi^{\tau}(e) + (1 + r)a \\ x &= \begin{cases} a' & \text{if stays in the traditional sector} \\ a' + \kappa - \theta \chi p(a', e) & \text{if enter in the modern sector.} \end{cases} \end{aligned}$$

where $\pi^{\tau}(e)$ is the profit of a producer in the traditional sector, and $p(a', e)$ is the price of a share.

Modern Sector

- Production function: $Y_t = \exp(z + e + \phi)^{1-\eta} (K_t^\alpha L_t^{1-\alpha})^\eta$, where $\phi \geq 0$.
- Producers in the modern sector are subject to the same collateral constraint of entrants.
- Bellman equation:

$$V^m(a, e) = \max_{a', c} \log(c) + \beta \mathbb{E}[V^m(a', e') | e]$$
$$\text{s.t. } c + a' = (1 - \theta\chi)\pi^m(a, e) + (1 + r)a$$

where profits $\pi^m(a, e)$ are given by:

$$\pi^m(a, e) = \max_{k, l} \exp(e + \phi)^{1-\eta} (k^\alpha l^{1-\alpha})^\eta - Wl - (r + \delta)k \quad \text{s.t.} \quad k \leq \frac{1}{1 - \theta}a + \frac{\theta}{1 - \theta}\kappa$$

- Workers choose consumption-savings. Savings can be in risk-free assets or shares from modern firms.
- Let ω_i be the number of shares from producer i , the budget constraint is:

$$c_t + a_{t+1} + \int P_t^i \omega_{t+1}^i di = W \gamma^t \nu_t + (1 + r) a_t + \int (P_t^i + \Pi_{t,}^{m,i}) \omega_t^i di$$

which implies a savings function and the no-arbitrage condition:

$$P_t = \frac{\mathbb{E}_t[P_t + \Pi_{t+1}^{m,i}]}{1 + r} \quad \Rightarrow \quad p(a, e) = \frac{\mathbb{E}[p(a', e') + \pi^m(a', e') | e]}{1 + r}.$$

Distribution

- Let $n_t^m(a, e)$ and $n_t^\tau(a, e)$ be the measure of modern and traditional producers.
- The evolution of the measure of modern producers follows:

$$n_{t+1}^m(A, e_j) = \int_A \sum_i f_{i,j} \mathbf{1}_{\{a^m(a, e_i) \in A\}} dn_t^m(a, e_i) + \int_A \sum_i f_{i,j} \mathbf{1}_{\{\xi(a, e_i)=1, a^{\tau,s}(a, e_i) \in A\}} dn_t^{\tau,s}(a, e_i)$$

where $\xi(a, e_i) = 1$ represents the decision of switching sector.

- The law-of-motion for the traditional sector:

$$n_{t+1}^\tau(A, e_j) = \int_A \sum_i f_{i,j} \mathbf{1}_{\{\xi(a, e_i)=0, a^\tau(a, e_i) \in A\}} dn_t^\tau(a, e_i) + (\gamma - 1) N_t \mathbf{1}_{\{0 \in A\}} \bar{f}_j$$

where \bar{f}_j is the invariant distribution associated to the Markov process of e .

Equilibrium

- Must solve for r and W that clear labor and assets markets:
- Let $l^m(a, e)$ and $l^\tau(a, e)$ the labor demand of producers, labor market clearing is:

$$L_t = \int_{A \times E} l^\tau(a, e) dn_t^\tau(a, e) + \int_{A \times E} l^m(a, e) dn_t^m(a, e)$$

where L_t is the amount of labor efficiency units supplied by workers.

- Let $a_{t+1}(a, e)$ the savings decision of entrepreneurs, and A_{t+1}^w aggregate worker savings, the asset market clearing:

$$A_{t+1}^w + \sum_{i=m, \tau} \int_{A \times E} a_{t+1}^i(a, e) dn_t^i(a, e) = \int_{A \times E} k_{t+1}^m(a, e) dn_{t+1}^m(a, e)$$

Financial Frictions

- What is the effect of financial frictions (i.e., low θ)?
- Distortions come from two channels:
- **Entry:**
 - ▶ Entrepreneur must pay entry cost κ in order to operate in the modern sector;
 - ▶ Need financing to pay these costs or use their own funding.
- **Allocations in the Modern Sector:**
 - ▶ Collateral constraint: producers with little collateral operates with small scale.

Financial Frictions: Misallocation in the Modern Sector

- The collateral constraint distorts allocations in the modern sector. Recall the static profit maximization:

$$\pi^m(a, e) = \max_{k, l} \exp(e + \phi)^{1-\eta} (k^\alpha l^{1-\alpha})^\eta - Wl - (r + \delta)k \quad \text{s.t.} \quad k \leq \frac{1}{1-\theta}a + \frac{\theta}{1-\theta}\kappa$$

- Let $\mu(a, e)$ be the multiplier of the collateral constraint. F.O.C imply:

$$MPK = \alpha \eta \frac{y(a, e)}{k(a, e)} = r + \delta + \mu(a, e)$$

$$MPL = (1 - \alpha) \eta \frac{y(a, e)}{l(a, e)} = W$$

- $\downarrow a$ or $\uparrow e \Rightarrow \uparrow \mu$: Low-collateral entrepreneurs operate with low $k(a, e)/l(a, e)$ than optimal \Rightarrow lower profits.

Financial Frictions: Misallocation in the Modern Sector

- The distortion also changes the returns of savings. Suppose a simplified two-period version:

$$\begin{aligned} & \max_{c, c', a'} \log(c) + \beta \mathbb{E}[\log(c') | e] \\ \text{s.t. } & c = \pi(a, e) + (1 + r)a - a' \quad \text{and} \quad c' = \pi(a', e') + (1 + r)a' \end{aligned}$$

- F.O.C implies in the modified Euler Equation:

$$\frac{1}{c(a, e)} = \beta \mathbb{E} \left[\left(1 + r + \frac{\partial \pi(a', e')}{\partial a'} \right) \frac{1}{c(a', e')} | e \right]$$

where $\partial \pi(a', e') / \partial a' > 0$ iff $\mu(a', e') > 0$.

- Constrained entrepreneurs have higher returns to savings.

Financial Frictions: Misallocation in the Modern Sector

FIGURE 1. DECISION RULES: MODERN SECTOR

Financial Frictions: Entry

- Recall that to enter the modern sector a producer must pay the entry cost κ , and receives an injection $\theta\chi p(a', e)$.
- In the absence of financial frictions, a productive entrepreneur decides to enter no matter what.
 - ▶ She can always borrow to finance a large fixed cost;
- If the financial frictions are high:
 - ▶ Producer cannot borrow to pay the fixed cost;
 - ▶ Money from equity is lower because future profits are lower;
- The entrepreneur must first accumulate funds and then decide to enter. A productive but poor producer will not operate a business.

Financial Frictions: Entry

FIGURE 2. DECISION TO ENTER MODERN SECTOR

Efficient Allocations

- TFP losses in the Modern sector can be found by aggregating producers:

$$Y = \exp(\phi)^{1-\eta} \underbrace{\frac{\left(\int_{i \in M} \exp(e_i) (r + \delta + \mu_i)^{-\frac{(1-\alpha)\eta}{1-\eta}} di \right)^{1-\alpha\eta}}{\left(\int_{i \in M} \exp(e_i) (r + \delta + \mu_i)^{\frac{\alpha\eta-1}{1-\eta}} di \right)^{(1-\alpha)\eta}}}_{=TFP} (K^\alpha L^{1-\alpha})^\eta$$

where M is the set of producers in the modern sector.

- The efficient TFP:

$$Y = \exp(\phi)^{1-\eta} \left(\int_{i \in M} \exp(e_i) di \right)^{1-\eta} (K^\alpha L^{1-\alpha})^\eta.$$

Efficient Allocations

- TFP losses from financial frictions in the modern sector arise from *dispersion in the shadow cost of funds* $\mu(a, e)$.
- The previous equations kept fixed the measure M .
- To compute the fully *efficient (first-best) allocations* (i.e., allocation across modern and traditional sectors), one should solve and specify a planners' problem.
- The planner chooses the measure of producers in the two sectors n^T and n^m , and the stock of capital, subject to the resources available.
 - ▶ Check the paper for the full problem.

Data and Calibration

Data

- Korean manufacturing sector between 1991-1999;
- Information about revenue, wage bill, intermediate inputs, investment and capital stock for plants with more than five workers. Panel data.

Calibration

- Aggregate technology parameters from other studies and standard values $(\alpha, \eta, \delta, \beta, \gamma, \phi, \nu)$.
- Microdata on value-added to estimate productivity process; data on credit to calibrate θ and χ .
- Data on capital and labor is used to validate the model.

TABLE 1—MOMENTS

	Data Korea	Benchmark	Adoption	Exit
<i>Panel A. Used to calibrate model</i>

Consumption			1.01	0.91	0.87	0.84	0.82
Output			1.70	1.42	1.29	1.20	1.13

Discussion

- Benchmark Korea not very constrained (debt-to-GDP 120% $\Rightarrow \theta = 0.86$). Small effects on TFP and output:
 - ▶ Only 17% of the entrepreneurs are constrained.
 - ▶ Loss from misallocation is negligible (0.3%).
 - ▶ Entry is not distorted: fraction in the modern sector is the same in both efficient and “Korea”.
- Increase in financial frictions (i.e., $\downarrow \theta$):
 - ▶ Large impact on TFP and consumption (at most 17%).
 - ▶ Misallocation within the modern sector accounts for “only” 4.7%.
 - ▶ Most is due to **lack of entry** in the modern sector.
 - ▶ Potentially larger without the possibility of equity issuance ($\chi = 0$) and in a close economy (interest rate adjusts).
- Why misallocation from FF is low? Financially constrained producers *self-finance* and grow out the collateral constraint.

Microeconomics Implications

- There are several implications of financial frictions for some micro statistics.
- Financial frictions act like an adjustment cost by preventing constrained firms to adjust capital in response to changes in productivity.
 - ▶ Tighter friction reduces std. dev. of output growth.
- Financial frictions also disproportionately affect young producers who have not yet accumulated internal funds.
 - ▶ With FF, young firms tend to grow faster than old firms since they are accumulating capital.
- The last point may change if the model has technology adoption or endogenous exit.

Microeconomics Implications

TABLE 6—EXTENSIONS OF THE BENCHMARK MODEL

	“Korea”	No finance	“Korea”	No finance	“Korea”	No finance
Debt to output (modern)	1.2	−0.6	1.2	−0.2	1.2	−0.6
Equity to output (modern)	0.3	0	0.3	0	0.3	0
Consumption	1.00	0.82	1.41	0.97	0.86	0.79
Output	1.68	1.13	2.41	1.47	1.30	1.08
TFP modern sector	1	0.83	1.29	0.99	0.91	0.79
Loss misallocation, percent	0.3	4.7	1.2	6.3	2.1	4.1
Fraction producers modern	0.93	0.35	0.93	0.39	0.36	0.25
Fraction productive producers modern	—	—	0.86	0.18	—	—
Fraction modern producers operating	1	1	1	1	0.67	0.44
SD output growth	0.58	0.32	0.58	0.26	0.59	0.40
Average product of capital, 1–5 versus 11+	0.08	0.73	0.27	0.22	0.13	0.19
Relative output growth, 1–5 versus 11+	0.09	0.12	0.28	0.08	0.10	0.08

Note: First column is benchmark; second is model with technology adoption; third is with endogenous exit.

Conclusion

- Model of establishment dynamics in which financial frictions may distort aggregate productivity through two channels:
 - ▶ **Entry** (extensive margin);
 - ▶ **Misallocation within sector** (intensive margin).
- Financial frictions potentially generate large losses from inefficiently low levels of entry and technology adoption; but small losses from misallocation within operating producers.
- Why? Productive producers accumulate internal funds over time and quickly grow out of their borrowing constraints.
